# What is Gasification?

*Gasification is the partial combustion of Coal with  $O_2$  and water*

## ❖INPUTS

Coal

Oxygen/Air

Water

## ❖OUTPUTS

Synthesis/Fuel gas

$H_2, CH_4, CO, CO_2$

Char, Tar & Water

Heat

Underground coal gasification is like other coal gasification techniques (Sasol® FBDB™), except that the geological strata form the reaction vessel and groundwater is used as process chemical.

This lowers cost, but adds a level of complexity to analysis of the process behaviour and leads to extra uncertainty due the geological environment.

# What is UCG

**Underground Coal Gasification (UCG) is a cost-effective environmental friendly solution for resource recovery in areas beyond the technical and economic confines of conventional mining.**

**Employing a series of wells, UCG converts in-situ coal into product gas, thus eliminating the expense of:**

- Mining
- Blending
- Stockpiling
- Reclamation
- Road transport
- Screening
- Fine coal losses and dust pollution
- Surface gasifier operation and maintenance
- Ash handling

# Quick Process Description

- UCG involves injecting steam and air or  $O_2$  into a coal seam from a **injection well**. The injected gases react with coal to form a combustible gas which is brought to the surface in a **production well**, cleaned and used as a fuel or chemical feedstock.
- To facilitate flow of the gas through the coal seam from the combustion zone to the production well, a “**link**” is created by **using directional drilling**.
- At the initiation of a UCG operation, **ignition wells** are used to provide ignition agents (e.g. propane or LPG, burning wood or coal, ammonium nitrate fuel oil (ANFO), explosives like thermite, diesel and other fuels, air/steam/oxygen, etc.) to initiate combustion.
- Once combustion is established in the coal seam, the injection wells inject  $O_2$  to **sustain and control the combustion** rate.
- A **cavity is formed** as the coal burns and the **roof collapses / goaf**. This results in lateral growth and is allowed to continue until the product gas quality deteriorates.

# Quick Process Description

- Between the combustion zone and the production wells, the gas flows through the coal seam and is enriched by products of the reactions and pyrolysis.
- When the quality of the product gas falls, fresh coal is ignited further along the injection well. The **Injection Wells are often moved** in order to “guide” the combustion process between the wells and thereby create the desired link between the reaction zone and the production well.
- The greater the lateral growth, the longer the life of a gasifier and the more cost-effective the operation.
- Once the coal within the underground gasifier has been exhausted, new injection and production wells are drilled and the process is repeated.

# Zhangzhuang UCG Station

XinAo Group, China, 1990 to present

# The sketch of the “long-tunnel, large-section, two-stage” gasifier

# Rocky Mountain, US Trials 1987-1990

- 31 tests involving DOE, Gulf, Texas A&M, GRI, ARCO
- Two technologies developed
  - Steeply Dipping Beds
  - Moveable Injection = CRIP
- Rocky Mountain Trial, 14,000 tons of coal 93 days

# Joint European Trail, Spain

- ELW is 2 directionally drilled wells that intersect at an angle of 30°.
- Combustion was started at the intersection point from a vertical borehole, but it was assumed that in future this could be done through one of the directional boreholes
- One directional hole is used as injection hole and the other as Production hole.
- Gasifier life was short lived as chamber dies as it reached maximum sustainable size.
- Once dead it could not be started again

# Well Layout for Spanish Trial (CRIP)

FIGURE 5 Well Layout

# THE CHINCHILLA PROJECT

**Queensland, Australia**

- pilot scale
- operating Nov 1999 – Apr 2003 (in conservation mode at present)
- conversion to CTL proposed
- little visible infrastructure
- no groundwater /surface contamination \*
- no surface subsidence
- 1 week shutdown possible i.e. peaking capability with CCGT
- 100% availability
- 95% coal usage
- 75% energy recovery

\* By independent audit by Golder Associates, for Australian EPA

# Long-wall mining thinking applied to UCG

# Why Air vs. O<sub>2</sub>

Process	Efficiency
Air-blown UCG	45.4 %
Oxygen-blown UCG	46.5 %
UCG with CO <sub>2</sub> separation	39.8 %
Conventional coal	~37 %
IGCC	~45 %

## COAL RESOURCES INSITU

### AIR INJECTION

50% Nitrogen  
50% CO, H<sub>2</sub>, CH<sub>4</sub>, CO<sub>2</sub>  
100-180 BTU/ SCF

Electrical power generation &  
Industrial Fuel  
100-180 BTU / SCF

### STEAM/ OXYGEN INJECTION

100% CO, H<sub>2</sub>, CH<sub>4</sub>, CO<sub>2</sub>  
200-300 BTU/ SCF

#### CO<sub>2</sub> Removal

Synthesis Gas  
(Chemical Feedstock)  
300-400 BTU / SCF

#### CO shift and Methanation

Synthetic Pipeline Gas  
900 - 1000 BTU / SCF

## Oxygen is better for:

Increased CO:CO<sub>2</sub>  
ratio

Improves CV

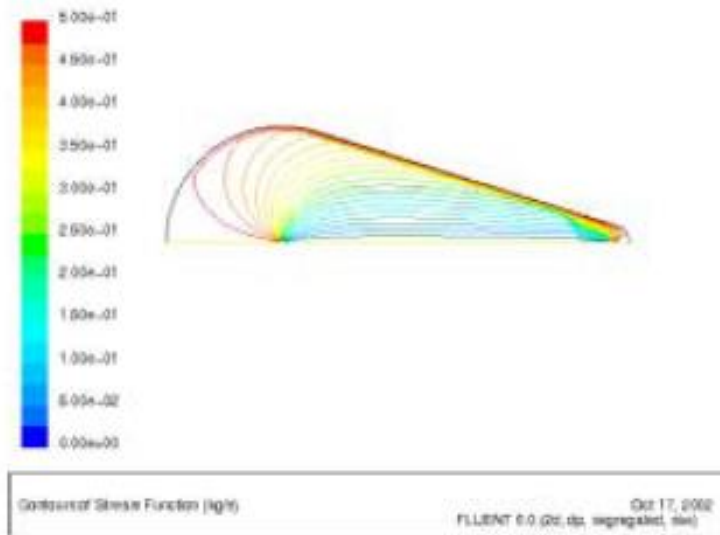

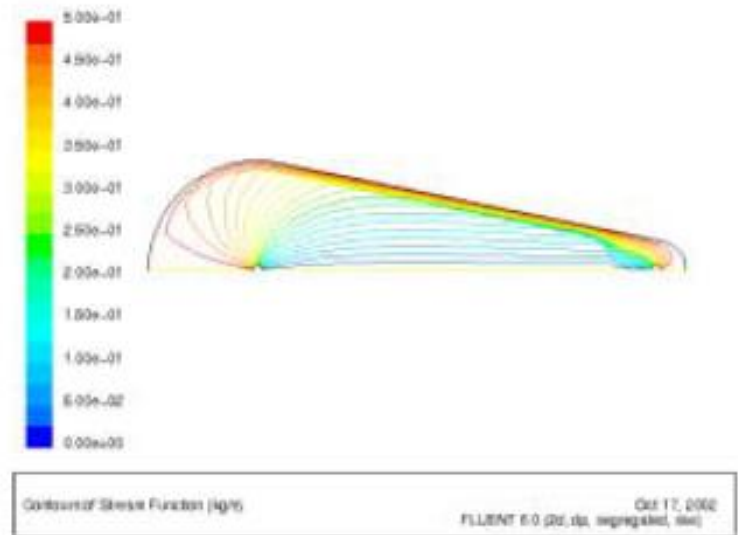

Improved gasification  
stability

Better cavity growth

60% reduction in  
volume of  
compressed gas  
injected into seam

- Underground (Oxygen)
- ◆ Underground (Steam)
- ▲ Natural gas

Carbon monoxide

Major combustible gas concentrations only

Synthesis gas

$H_2:CO = 1:1$

Synthesis gas

$H_2:CO = 2:1$

Hydrogen

Methane

# Opportunity definition for UCG

1. Utilisation of isolated deep coal reserves which can not be otherwise economically exploited
2. Increased efficiency of fossil fuel use (up to 95%)
3. Extension of mine life through optimal coal utilisation
4. Reduction of environmental footprint (no coal or ash handling required)
5. Mining-related hazards are avoided
